2011/3/11 14:46, Depth 24km, M9.0 (JMA)

The largest peak ground acceleration among K-NET and KiK-net sites was recorded at MYG004 K-NET station (waveforms displayed below), reaching 2933 gals (3 components vector summation).
Comparison of observed values of PGA and PGV with ground motion empirical attenuation laws (preliminary)

2011/03/11 14:46 Depth=24km(JMA), Mw=8.9(USGS)

- PGA and PGV were obtained as the maximum values between horizontal components.
- Observed PGV values were corrected to a Vs=600m/s, by removing the amplification at every station from boring information.
- The Mw8.9 is beyond the range of applicability of the empirical attenuation laws (Shi and Midorikawa,1999)
- The fault model used is preliminary

Assumed fault model

Velocity Response Spectra (1% damping)
Near-source acceleration waveforms display two remarkable phases of ground motion which suggest the existence of a least two areas of large slip. In the northern part of the source area the first phase is predominant while in the South this phase is not visible. These two phases of ground motion suggest large slip areas in the North and South regions respectively.

The remarkable differences in grow characteristics of intensity values for the Miyagi and Ibaraki regions indicate they originate from different slip areas. A small ground motion phase is observed between the two large distinct phase at some stations (FKS013, FKS004, MYG017, MYG015).

Other secondary phases are also observed suggesting a very complex source process.
Source Process of the 2011 Off the Pacific Coast of Tohoku earthquake based on Strong Ground Motions (Preliminary)
National Research Institute for Earth Science and Disaster Prevention

○ Fault Model
- Strike : 195 degrees
- Dip : 13 degrees
- Size : 510km × 210km

○ Results
- M0 : 3.28 × 10²³ Nm (Mw8.9)
- Largest slip : 23m

This is a preliminary result and it will be updated.

Figure 1 : Stations used for inversion (Red: K-NET stations, Blue: KiK-net borehole stations) and slip distribution. A red arrow displays the epicenter.

Figure 2 : Slip distribution. Contour lines of slip every 5 m are displayed. The arrows show the slip directions and amplitudes of the hanging wall.
