

# PEER-CEA Wood-Frame Project: Numerical Simulations

---

Dr. David Welch

Post-Doctoral Researcher

Stanford University

# Outline

---

- End Goals and Numerical Framework
  - FEMA P-1100 to PEER-CEA
  - FEMA P-58 Performance Assessment Process
- What to Analyze?
  - Definition of Building Variants and Index Configurations
- How to Analyze?
  - Selected Sites and Ground Motions
  - Structural Modeling
  - Damage and Consequence Modeling for Older Wood-frame
- Example Results and Observed Trends

# FEMA P-1100 to PEER-CEA

- The **FEMA P-1100** Prestandard (ATC-110 Project) represents the **engineering solution** to the unbraced cripple wall problem (**collapse prevention**)
- The **PEER-CEA Project** aims to understand what can be gained by adopting the engineering solution to **promote implementation** (**performance quantification**)

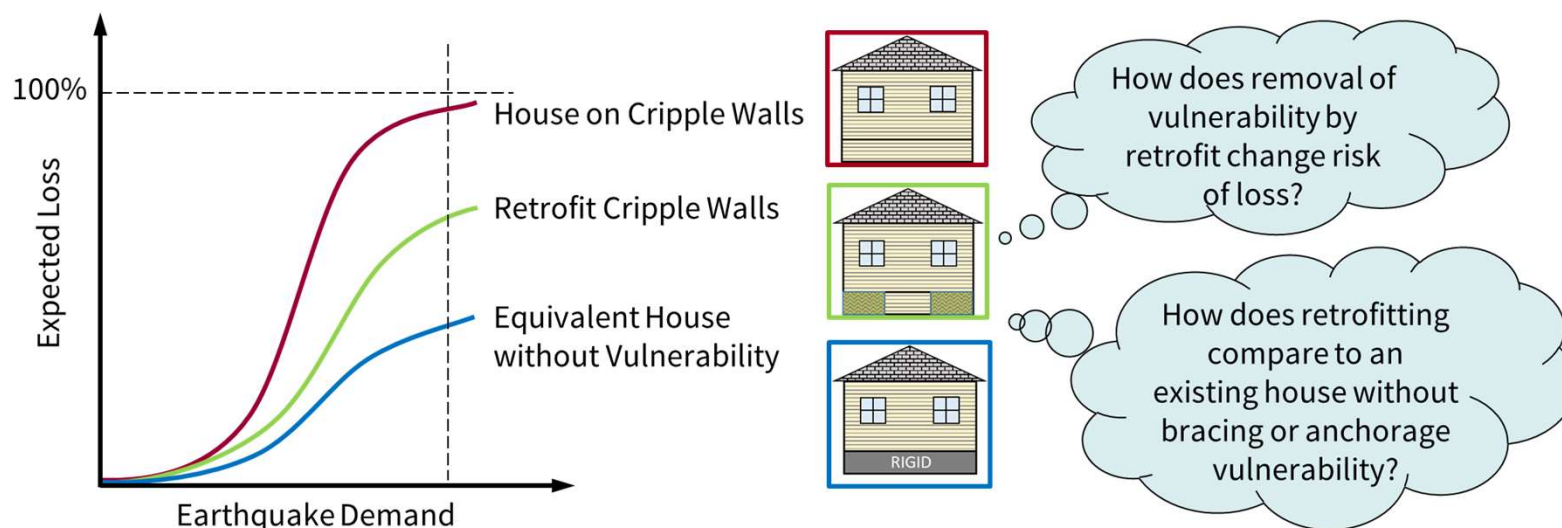

Reduced Vulnerability

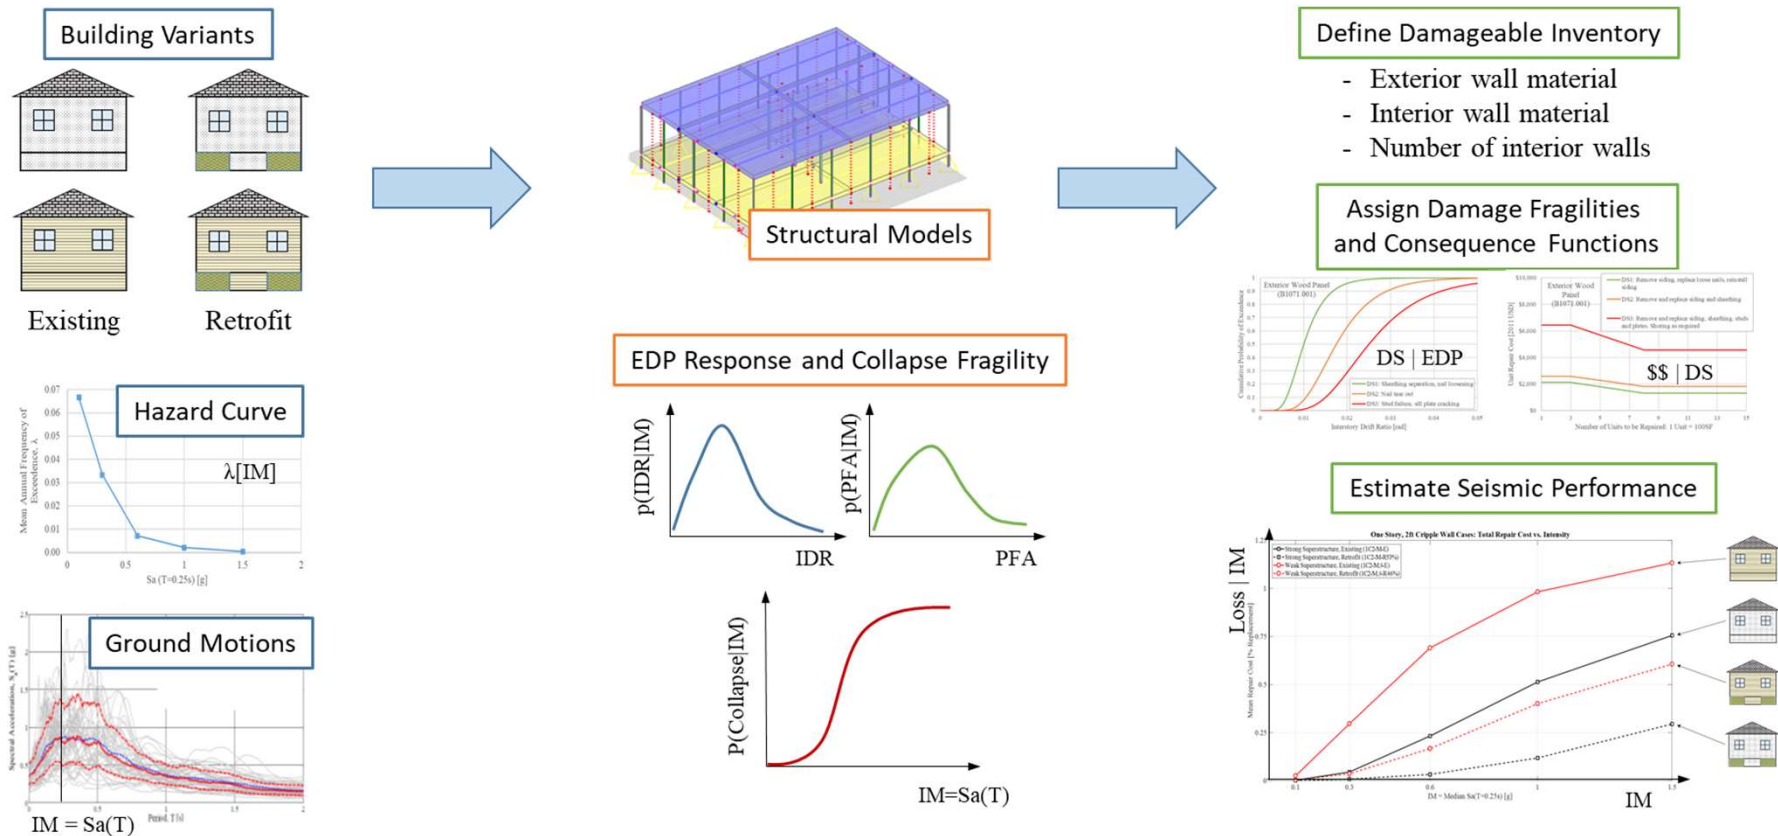

# End Goals for Numerical Simulations

- Establish adjustment factors to relate the *change* in seismic loss due to retrofitting at different intensity levels
- Develop loss functions to quantify the effect of retrofit considering observable and unobservable variants used in the insurance industry

# Overview of Building-Specific PBEE Framework (FEMA P-58)

# What to Analyze?

## Definition of Building Variants

---

- **Primary Variants - Observable**
  - Age of Construction
  - Number of Stories
- **Secondary Variants - Observable**
  - Exterior material
  - Building (roof) weight
  - Sill bolting
  - Cripple wall height/ slope differential
- **Secondary Variants - Unobservable**
  - Siding/Sheathing Combinations
  - Construction Quality and Condition

Credit: Evan Reis, Working Group 2 - Index Buildings

# What to Analyze?

## Definition of Building Variants

Construction Era (3):    Pre-1940                      1940-1955                      1956-1970

Interior/  
Sill Anchorage:

Exterior:

Cripple Wall Classification:

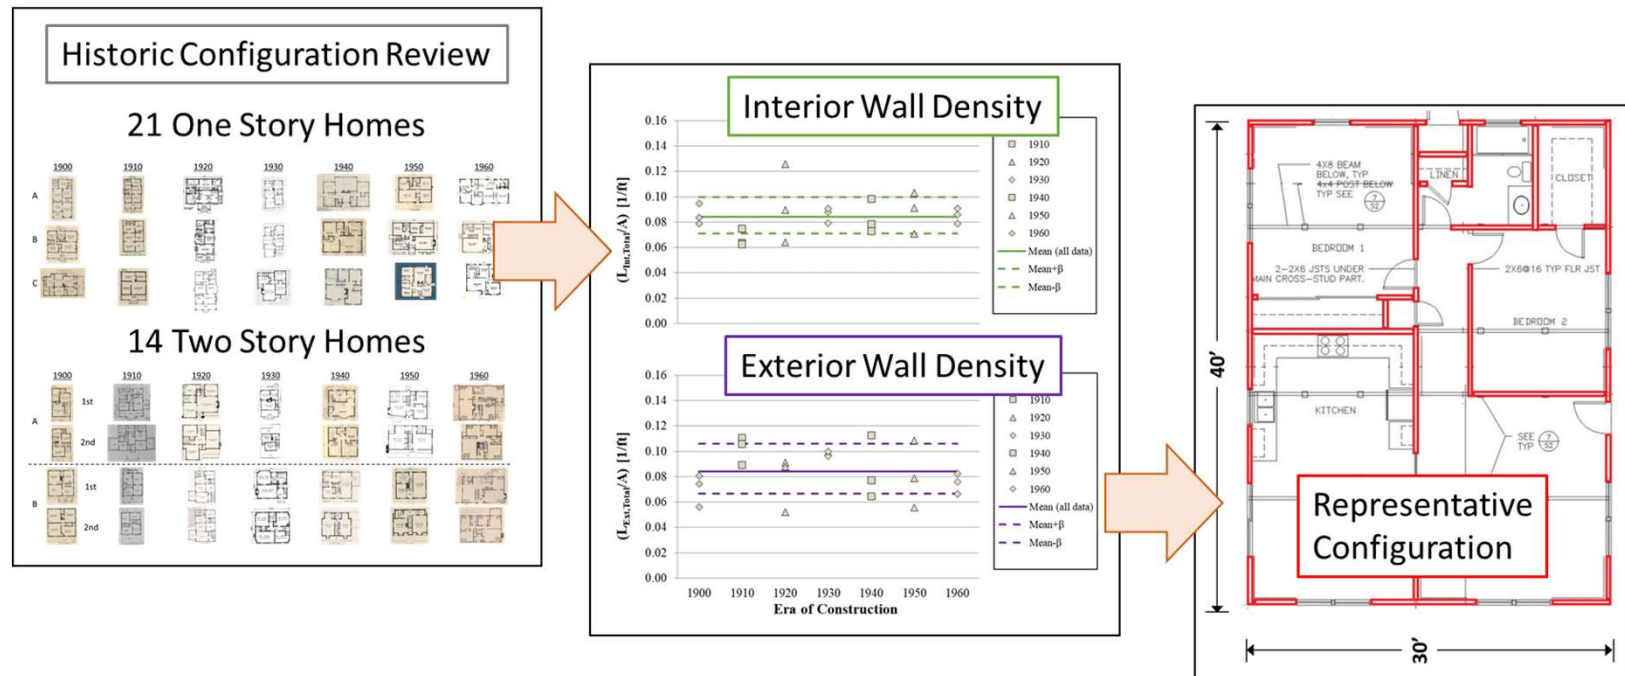

Credit: Evan Reis, Working Group 2 - Index Buildings

# What to Analyze?

## Baseline Superstructure Configurations

- Wall configuration affects the strength, stiffness, weight and damageable quantities within a home
- ATC-110 configuration collection was used to obtain statistics on interior and exterior wall density

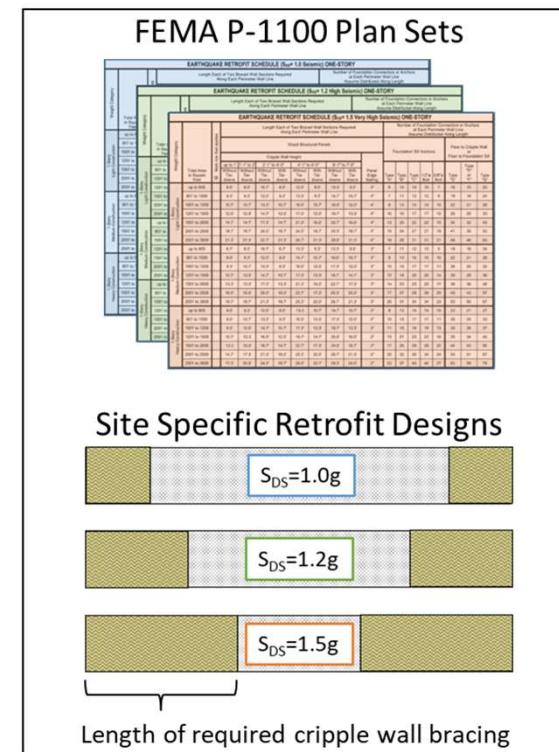

Collaborator: Colin Blaney, ATC-110, PEER-CEA Project Reviewer

# How to Analyze?

## Selected Building Sites and Ground Motions

- 4 baseline sites adopted ( $V_{s,30}=270\text{m/s}$ )
- Covers seismicity range in FEMA P-1100

Credit: Silvia Mazzoni and Yousef Bozorgnia, Working Group 3 - Ground Motions (Group leaders)

# How to Analyze?

## Selected Building Sites and Ground Motions

- 4 baseline sites adopted ( $V_{s,30}=270\text{m/s}$ )
- Covers seismicity range in FEMA P-1100
- 10 intensities per site (RP=15y to 2500y)
- 45 ground motion pairs per intensity selected to match target Conditional Mean Spectrum ( $T^*=0.25\text{s}$ )

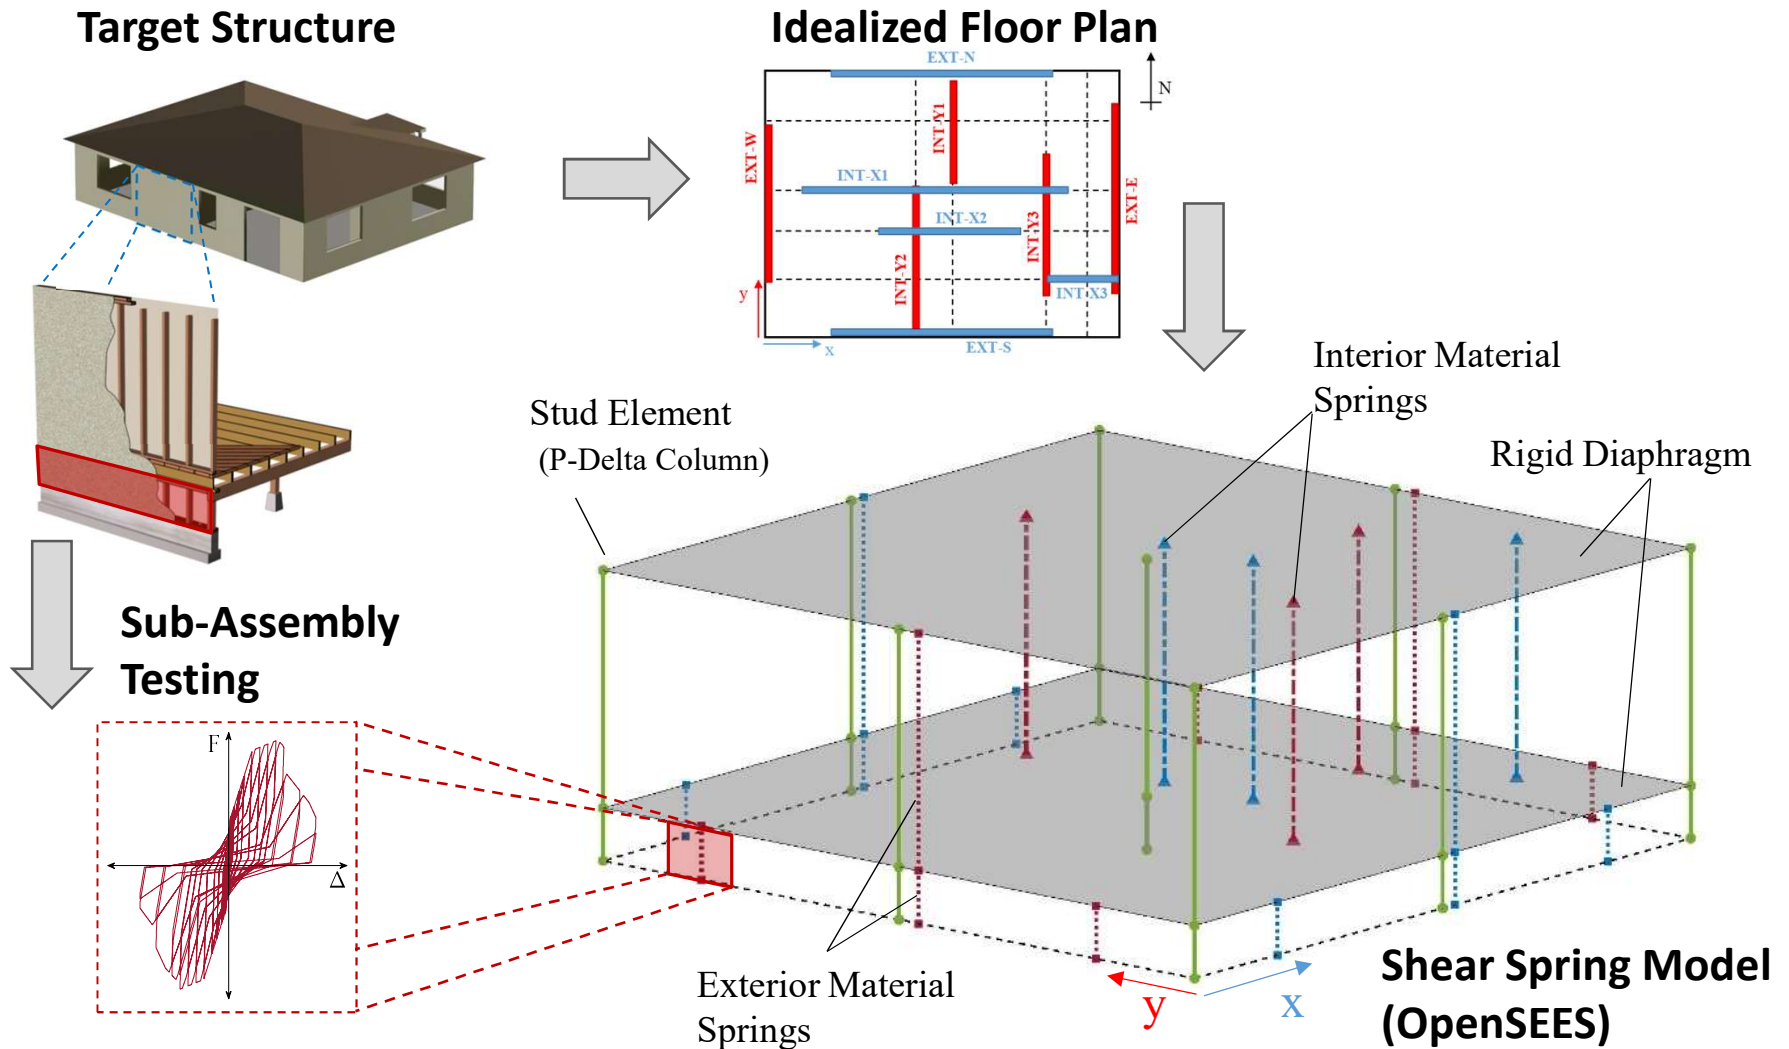

Example CMS:  
San Francisco 270 site

Credit: Silvia Mazzoni and Yousef Bozorgnia, Working Group 3 - Ground Motions (Group leaders)

# How to Analyze? Structural Modeling (OpenSEES)

# How to Analyze?

## Hysteretic Modeling of Wall Materials

2ft X 12ft cripple wall with **horizontal wood siding** (PEER-CEA Test A7)

Test Data:  
Schiller & Hutchinson, UCSD

## Numerical

## Pinching4

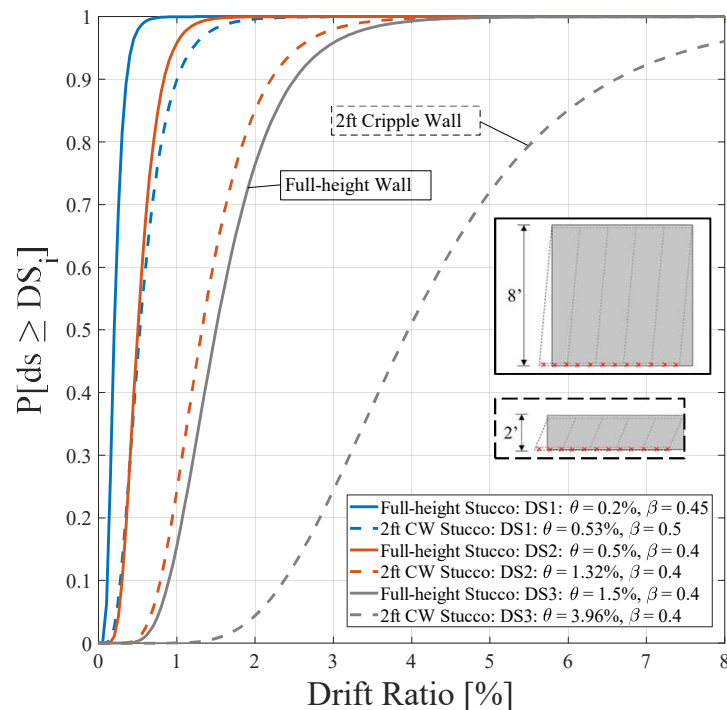

## 2 Spring Material

# How to Analyze?

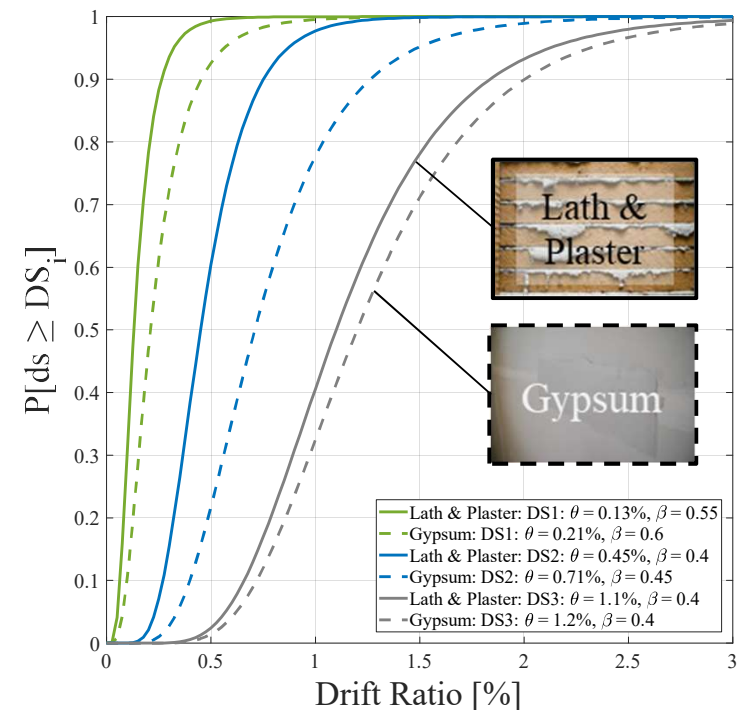

## Damage Analysis of Older Wood-frame

- Review and Modification of FEMA P-58 Database
- Updating Existing Component Fragilities (based on testing)

Median Drift Adjustment  
for Shorter Stucco Walls

Gypsum vs. Lath and Plaster Fragility

# How to Analyze?

## Consequence Modeling of Older Wood-frame

---

- **Claims Adjustor Damage Workshop** (February/March 2019)
  - Obtained **repair cost estimates** from practicing claims adjustors with earthquake damage experience
  - **Slight Damage to Complete Replacement**
  - Damage states in line FEMA P-58 where applicable (Comparison to existing P-58 information)
  - Case studies **target materials with large knowledge gaps** in terms of repair costs (Expand Applicability)
  - Survey questions (Experience data)

Credit: Bret Lizundia, Workshop Organizer

# Example Results and Trends

## Consider four variants:

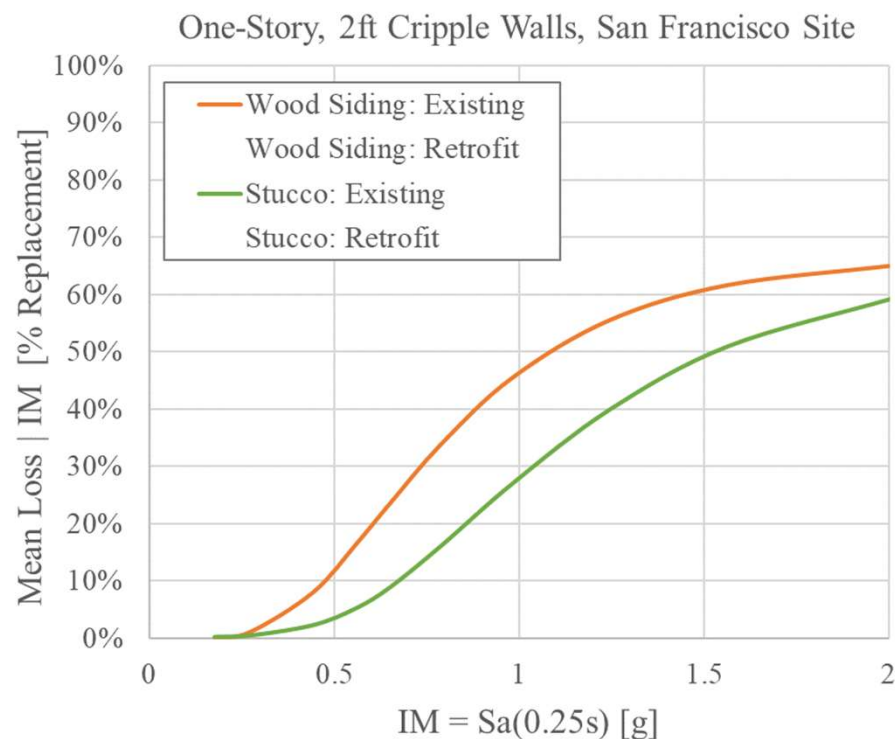

- One- and Two-Story
- Wood Siding and Stucco Exterior
- Post-1955 era (Gypsum Interior)
- 2-foot Level Cripple Walls
- Located in San Francisco

## Key Performance Results:

- Mean Loss vs. Intensity Curve
- Expected Annual Loss
- Mean Loss at 250yr Hazard Intensity

# Example Results and Trends

Expected Annual Loss

Loss versus Intensity (SF Site)

Loss at 250yr Hazard Intensity

# Example Results and Trends

Loss versus Intensity (SF Site)

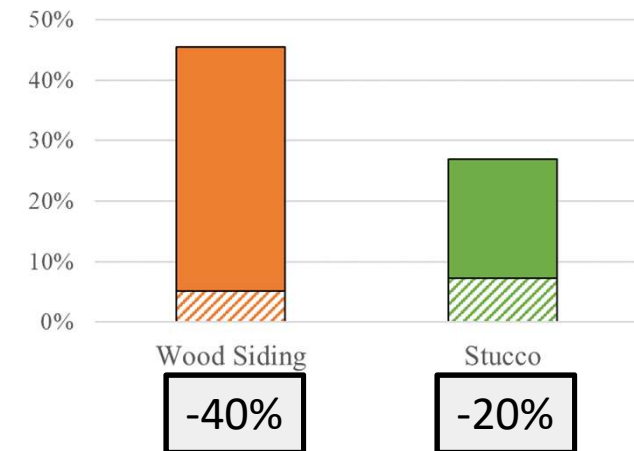

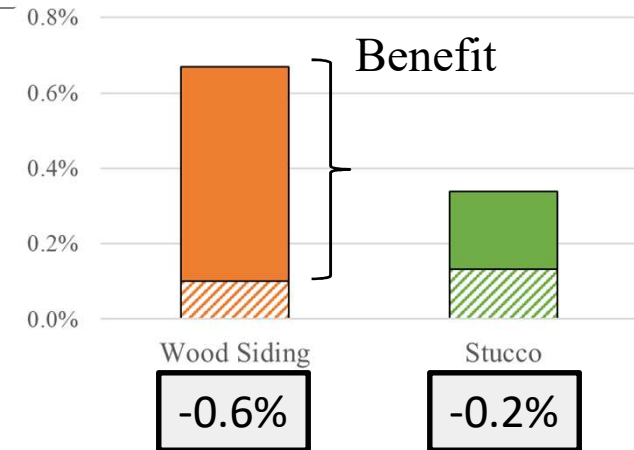

Loss at 250yr Hazard Intensity

# Example Results and Trends

Loss versus Intensity (SF Site)

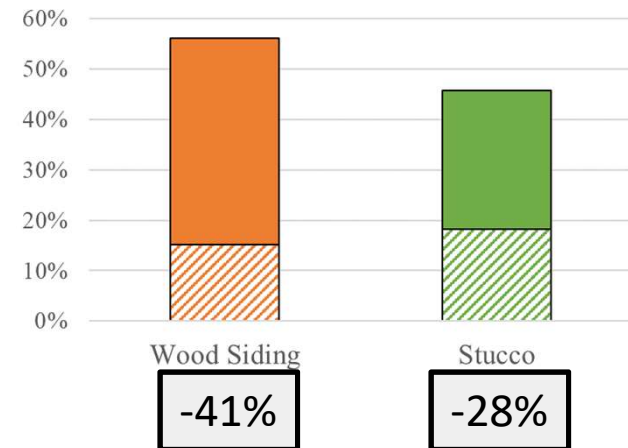

# Example Results and Trends

$S_{a,RP=250} = 1.0g$

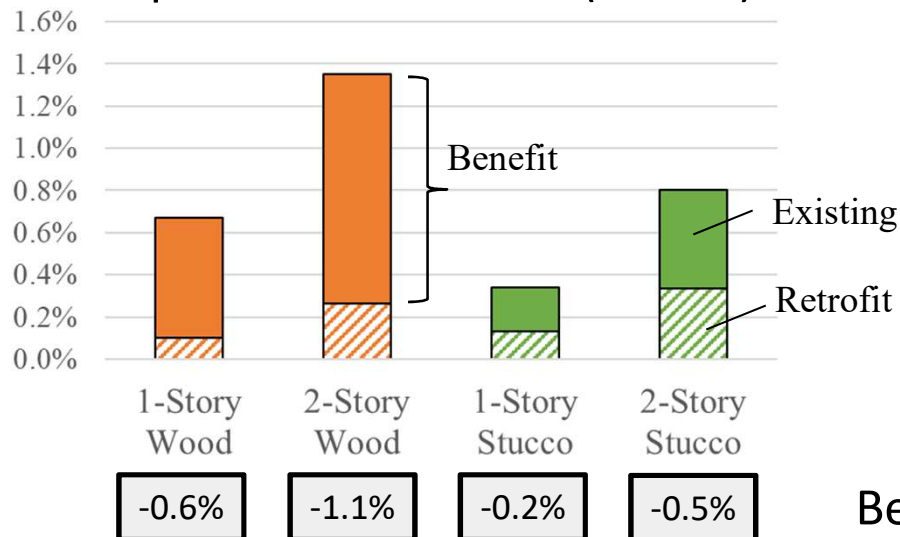

Loss versus Intensity (SF Site)

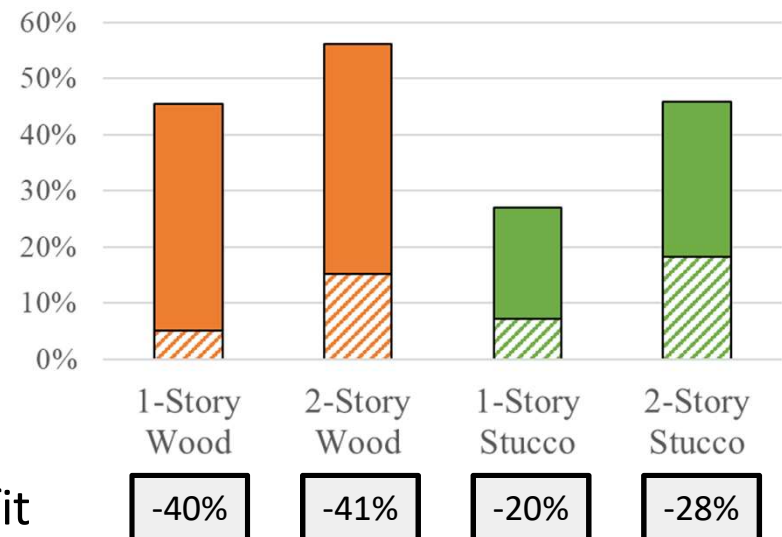

# Example Results and Trends

- Lower cripple wall strength increases observed retrofit benefit
- Two-story perform worse than one-story (existing and retrofit)
- Observed benefits due to retrofitting vary significantly depending on building variant and loss metric

Expected Annual Loss (SF Site)

Loss at 250yr Hazard Intensity (SF Site)

# Thank you for your attention!
